The Purpose and Importance of AISC Table 3-2

AISC Table 3-2, officially titled "Allowable Stress Design (ASD) Strength", is a cornerstone of the AISC Steel Construction Manual. Its primary purpose is to provide designers with the permissible stress values for various types of structural steel members under different loading conditions. This allows engineers to design steel components that will not exceed their elastic limits under expected service loads, thereby preventing permanent deformation or failure. The ASD method, which is still widely used, relies on applying factors of safety to the ultimate strength of materials to determine allowable stresses. This approach ensures that the stresses induced in a structure by normal operating loads are well below the point where the steel would yield or fracture. Therefore, a thorough understanding of AISC Table 3-2 is paramount for any professional involved in structural steel design and construction, as it directly impacts the safety and reliability of the built environment.

Key Components and Columns of AISC Table 3-2

AISC Table 3-2 is organized systematically to present a wealth of information in a digestible format.

Each row typically represents a specific steel shape or type of connection, while the columns provide the corresponding allowable stress values for different stress states. Understanding these columns is crucial for accurate application. Common columns you will encounter in AISC Table 3-2 include:

- **Member Type/Description:** This column identifies the specific structural element or connection being referenced. This could range from wide-flange beams and columns to pipes, angles, and various connection types like bolts and welds.
- **Allowable Tensile Stress (F_t):** This value indicates the maximum tensile stress that the steel material can withstand without yielding. It's a critical consideration for members subjected to pulling forces.
- **Allowable Compressive Stress (F_c):** This specifies the maximum compressive stress permissible. This is particularly important for columns and other members experiencing pushing forces, where buckling is a significant concern.
- **Allowable Shear Stress (F_v):** This column defines the maximum shear stress the material can handle. Shear stress is prevalent in beams, especially near supports, and in connections.
- **Allowable Bearing Stress (F_p):** This value relates to the stress a material can withstand when it is in direct contact with another surface, such as the bearing of a beam on a column or a bolt in a hole.

The specific columns and their exact designations may vary slightly depending on the edition of the AISC Steel Construction Manual, but these represent the core stress categories commonly found. Each value is derived based on material properties and safety factors defined within the AISC specifications.

Understanding Stress Categories within AISC Table 3-2

The strength of structural steel is not just a single number but a complex interplay of how it behaves under different types of loads. AISC Table 3-2 categorizes these behaviors into distinct stress types, each with its own allowable limit to prevent failure. Mastering these categories is fundamental to effective structural design using ASD principles.

Allowable Tensile Stress

Tensile stress occurs when a material is pulled or stretched. In steel structures, this can be seen in members like bottom chords of trusses, or tension hangers. AISC Table 3-2 provides the maximum tensile stress that can be applied without the steel permanently deforming (yielding) or breaking. This value is often directly related to the yield strength of the steel grade.

Allowable Compressive Stress

Compressive stress is the opposite of tensile stress; it occurs when a material is pushed or squeezed. Columns are the most common example of members under compression. However, unlike simple tension, compression members are also susceptible to buckling – a sudden loss of stability that can occur long before the material itself reaches its compressive strength. AISC Table 3-2 accounts for this by providing allowable compressive stress values that are often reduced from the basic material compressive strength to account for buckling potential, which is dependent on the member's geometry and support conditions.

Allowable Shear Stress

Shear stress arises when forces act parallel to a surface, causing one part of the material to slide relative to another. In beams, significant shear forces are typically concentrated near the supports. Web crippling and web yielding in beams are also related to shear and bearing stresses. AISC Table

3-2 specifies the maximum allowable shear stress to prevent failure from these sliding forces.

Allowable Bearing Stress

Bearing stress is encountered where one structural element rests on another, or where fasteners like bolts are seated in holes. This stress is about the resistance to crushing. For instance, the end of a beam resting on a column experiences bearing stress. AISC Table 3-2 provides allowable bearing stress values to ensure that neither the supporting nor the supported element is crushed under the applied load.

Application of AISC Table 3-2 in Structural Steel Design

The application of AISC Table 3-2 is a critical step in the structural design process. Once a structural engineer has determined the expected loads on a steel member (such as dead loads, live loads, wind loads, and seismic loads), they can calculate the internal forces and stresses acting on that member. This involves using principles of mechanics of materials and structural analysis.

Following the calculation of these stresses, the engineer then refers to AISC Table 3-2 to find the appropriate allowable stress value for the specific steel shape and material grade being used. The fundamental principle of the ASD method is that the calculated stress in the member must be less than or equal to the allowable stress value provided in the table. This ensures that a sufficient factor of safety is maintained.

For example, if a steel column is calculated to experience a maximum compressive stress of 20 ksi, and AISC Table 3-2, for that specific column shape and material, lists an allowable compressive stress of 25 ksi, then the design is deemed adequate for that particular load condition. If the calculated stress were to exceed the allowable stress, the engineer would need to select a larger or stronger steel shape, or re-evaluate the load paths and potentially modify the structural system.

Factors Influencing Allowable Stress Values

The allowable stress values presented in AISC Table 3-2 are not arbitrary figures. They are carefully determined based on a variety of factors that influence the performance and strength of structural steel. Understanding these influencing factors provides deeper insight into the rigor behind the table's provisions.

- **Material Properties:** The fundamental strength of the steel, characterized by its yield strength (F_y) and ultimate tensile strength (F_u), is the primary determinant of allowable stresses. Higher strength steels generally permit higher allowable stresses.
- **Member Geometry:** The shape and dimensions of a steel member significantly affect its load-carrying capacity, particularly in compression and bending. Slenderness ratios (the ratio of length to cross-sectional dimension) are crucial for determining buckling behavior in compressive members.
- **Load Combinations:** While AISC Table 3-2 provides allowable stresses for individual stress types, engineers must also consider combinations of loads. The AISC specifications outline load combinations and their associated safety factors.
- **Buckling Potential:** As mentioned, buckling is a critical failure mode for compression members. The allowable compressive stress is significantly influenced by the member's effective length and its cross-sectional properties that resist buckling.
- **Weld and Bolt Strength:** For connections, the allowable stresses for welds and bolts are also detailed in AISC specifications, often in tables similar to or cross-referenced with Table 3-2, ensuring the connection is as strong as, or stronger than, the connected members.
- **Type of Stress:** Different types of stress (tension, compression, shear, bearing) have different

failure mechanisms and therefore require different allowable stress limits.

Material Grades and Their Impact on AISC Table 3-2

Structural steel is produced in various grades, each defined by its chemical composition and mechanical properties, most notably its yield strength (F_y). AISC Table 3-2 is designed to be flexible enough to accommodate these different grades. When an engineer designs a structure, they must specify the grade of steel to be used. This specification directly influences which allowable stress values from Table 3-2 are applicable.

For instance, ASTM A36 steel is a common, lower-strength structural steel with a specified minimum yield strength of 36 ksi. In contrast, ASTM A992 steel, often used for structural beams, has a minimum yield strength of 50 ksi. Consequently, for the same geometric section and the same type of stress (e.g., bending), the allowable stress value derived from AISC Table 3-2 for A992 steel will be higher than that for A36 steel, allowing for a more efficient use of material and potentially smaller member sizes.

It is imperative for designers to accurately identify the steel grade specified for a project and then correctly extract the corresponding allowable stress values from AISC Table 3-2. Using incorrect or outdated material information can lead to under-designed or over-designed structures, both of which have serious implications for safety and cost-effectiveness.

Common Misconceptions and Best Practices

Despite its importance, there are several common misconceptions and areas where designers may falter when using AISC Table 3-2. Adhering to best practices can mitigate these issues and ensure

robust designs.

- **Confusing ASD with LRFD:** AISC Table 3-2 specifically pertains to the Allowable Stress Design (ASD) method. The Load and Resistance Factor Design (LRFD) method, also covered by AISC, uses different principles and has its own set of strength provisions. Designers must be clear about which design method they are employing.
- **Overlooking Local Buckling:** While AISC Table 3-2 accounts for global buckling of columns, local buckling of thin flange or web elements within a cross-section can also occur. The Manual includes provisions and checks for these phenomena, often tied to the classification of the cross-section (compact, non-compact, or slender).
- **Not Considering Combined Stresses:** Many structural members experience multiple types of stress simultaneously (e.g., bending and axial load). AISC provides interaction equations to check the capacity of members under combined stresses, which are crucial extensions of the basic allowable stress provisions.
- **Using Outdated Manual Editions:** AISC periodically updates its Steel Construction Manual. It is vital for engineers to use the most current edition to ensure compliance with the latest codes and best practices.
- **Misinterpreting Note and Footnotes:** AISC Table 3-2 and the surrounding text often contain important notes and footnotes that qualify the application of the table values. These must be read and understood to ensure correct application.

Best practices involve a thorough understanding of the entire AISC Steel Construction Manual, not just isolated tables. Continuous education and attention to detail are key to successfully implementing the provisions of AISC Table 3-2 in real-world structural engineering projects.

The intricate details within AISC Table 3-2 are fundamental to the safe and efficient design of steel structures. By understanding its purpose, its components, and the factors that influence the allowable stresses, engineers can confidently specify steel members that meet rigorous safety standards. The continuous evolution of steel technology and design practices underscores the importance of staying current with the AISC specifications, ensuring that our built environment remains both resilient and economical.

H2: Understanding Yield Strength (F_y) and Tensile Strength (F_u)

Yield strength (F_y) represents the stress at which a material begins to deform plastically. This is a crucial parameter in structural design because it defines the limit of elastic behavior. Exceeding the yield strength leads to permanent deformation, which is generally undesirable in structural applications. Tensile strength (F_u), on the other hand, represents the maximum stress a material can withstand before fracturing. While important, it's less directly used in design than F_y because structures are typically designed to remain within the elastic range.

H2: Navigating AISC Table 3-2: A Practical Walkthrough

AISC Table 3-2 typically lists steel grades (e.g., A992, A572 Grade 50), along with their corresponding F_y and F_u values, often expressed in ksi (kips per square inch) or MPa (megapascals). Understanding the table's arrangement is vital. For instance, you'll find columns for different steel grades, each row specifying relevant properties. It's important to note that the values presented may vary based on the edition of the AISC specification. Always refer to the most current version for

accurate data.

H2: Applying AISC Table 3-2 in Design Calculations: Practical Examples

Let's consider a simple example: designing a rectangular steel beam. The first step involves determining the required moment capacity. Then, using appropriate formulas and selecting a steel grade (referencing AISC Table 3-2 for F_y), you can calculate the required section modulus (S). This allows you to choose a suitable beam section from a steel manual, ensuring that the selected section has a section modulus greater than or equal to the calculated requirement.

H2: Choosing the Right Steel Grade: Cost vs. Performance

The selection of steel grade is a critical decision balancing cost and performance. Higher strength steels (higher F_y) allow for smaller sections, potentially saving material costs. However, higher-strength steels might be more expensive per unit weight, and weldability could be affected. AISC Table 3-2 enables engineers to make informed decisions, weighing these trade-offs to arrive at an optimal design solution.

H2: Recent Advancements and Future Trends

Research continues to explore new steel alloys and manufacturing processes. These advancements lead to the development of higher-strength, more durable, and potentially more sustainable steel grades. AISC Table 3-2 will likely be updated to reflect these developments, ensuring that engineers have access to the most up-to-date information for optimal design.

aisc table 3 2: Architecturally Exposed Structural Steel Terri Meyer Boake, 2015-02-17
This book provides the means for a better control and purposeful consideration of the design of Architecturally Exposed Structural Steel (AESS). It deploys a detailed categorization of AESS and its uses according to design context, building typology and visual exposure. In a rare combination, this approach makes high quality benchmarks compatible with economies in terms of material use, fabrication methods, workforce and cost. Building with exposed steel has become more and more popular worldwide, also as advances in fire safety technology have permitted its use for building tasks under stringent fire regulations. On her background of long standing as a teacher in architectural steel design affiliated with many institutions, the author ranks among the world's best scholars on this topic. Among the fields covered by the extensive approach of this book are the characteristics of the various categories of AESS, the interrelatedness of design, fabrication and erection of the steel structures, issues of coating and protection (including corrosion and fire protection), special materials like weathering steel and stainless steel, the member choices and a connection design checklist. The description draws on many international examples from advanced contemporary architecture, all visited and photographed by the author, among which figure

buildings like the Amgen Helix Bridge in Seattle, the Shard Observation Level in London, the New York Times Building and the Arganquela Footbridge.

aisc table 3 2: Structural Steel Design to Eurocode 3 and AISC Specifications Claudio Bernuzzi, Benedetto Cordova, 2016-02-25 Structural Steel Design to Eurocode 3 and AISC Specifications deals with the theory and practical applications of structural steel design in Europe and the USA. The book covers appropriate theoretical and background information, followed by a more design-oriented coverage focusing on European and United States specifications and practices, allowing the reader to directly compare the approaches and results of both codes. Chapters follow a general plan, covering: A general section covering the relevant topics for the chapter, based on classical theory and recent research developments A detailed section covering design and detailing to Eurocode 3 specification A detailed section covering design and detailing to AISC specifications Fully worked examples are using both codes are presented. With construction companies working in increasingly international environments, engineers are more and more likely to encounter both codes. Written for design engineers and students of civil and structural engineering, this book will help both groups to become conversant with both code systems.

aisc table 3 2: Structure for Architects Ashwani Bedi, Ramsey Dabby, 2019-07-11 Structure for Architects: A Case Study in Steel, Wood, and Reinforced Concrete Design is a sequel to the authors' first text, Structure for Architects: A Primer, emphasizing the conceptual understanding of structural design in simple language and terms. This book focuses on structural principles applied to the design of typical structural members—a beam, a girder, and a column—in a diagrammatic frame building. Through the application of a single Case Study across three key materials, the book illustrates the theory, principles, and process of structural design. The Case Study progresses step-by-step for each material, from determining tributary areas and loads through a member's selection and design. The book addresses the frequent disparity between the way architects and engineers perceive and process information, with engineers focusing on technical aspects and architects focusing on visual concepts. Structure for Architects: A Case Study in Steel, Wood, and Reinforced Concrete Design presents readers with an understanding of fundamental engineering principles through a uniquely thematic Case Study. Focusing on the conceptual understanding of structural design, this book will be of interest to architecture students and professionals looking to understand the application of structural principles in relation to steel, wood, and concrete design.

aisc table 3 2: *Design of Steel Structures* Elias G. Abu-Saba, 2012-12-06 This book is intended for classroom teaching in architectural and civil engineering at the graduate and undergraduate levels. Although it has been developed from lecture notes given in structural steel design, it can be useful to practicing engineers. Many of the examples presented in this book are drawn from the field of design of structures. Design of Steel Structures can be used for one or two semesters of three hours each on the undergraduate level. For a two-semester curriculum, Chapters 1 through 8 can be used during the first semester. Heavy emphasis should be placed on Chapters 1 through 5, giving the student a brief exposure to the consideration of wind and earthquakes in the design of buildings. With the new federal requirements vis a vis wind and earthquake hazards, it is beneficial to the student to have some understanding of the underlying concepts in this field. In addition to the class lectures, the instructor should require the student to submit a term project that includes the complete structural design of a multi-story building using standard design procedures as specified by AISC Specifications. Thus, the use of the AISC Steel Construction Manual is a must in teaching this course. In the second semester, Chapters 9 through 13 should be covered. At the undergraduate level, Chapters 11 through 13 should be used on a limited basis, leaving the student more time to concentrate on composite construction and built-up girders.

aisc table 3 2: *Steel - A New and Traditional Material for Building* Dan Dubina, Viorel Ungureanu, 2006-08-17 In an era of new, composite materials and high-strength concrete, and with an increasing demand for sustainable building technologies, the importance of the role of steel in construction is being challenged.. Nonetheless, steel can successfully be used to refurbish and retrofit historical buildings, as well as being a material of choice for new building structures. Steel can effectively be combined with a variety of other materials to obtain structures which are characterized by a high-performance response under different types of static and dynamic activity. The proceedings contains nine keynote lectures from international experts, and is further divided into five sections: calculation models and methods; studies and advances in design codes; steel and mixed building technology; steel under exceptional actions; and steel in remarkable constructions and refurbishment.

aisc table 3 2: *Foundation Engineering Handbook* Hsai-Yang Fang, 2013-06-29 More than ten years have passed since the first edition was published. During that period there have been a substantial number of changes in geotechnical engineering, especially in the applications of foundation engineering. As the world population increases, more land is needed and many soil deposits previously deemed unsuitable for residential housing or other construction projects are now being used. Such areas include problematic soil regions, mining subsidence areas, and sanitary landfills. To overcome the problems associated with these natural or man-made soil deposits, new

and improved methods of analysis, design, and implementation are needed in foundation construction. As society develops and living standards rise, tall buildings, transportation facilities, and industrial complexes are increasingly being built. Because of the heavy design loads and the complicated environments, the traditional design concepts, construction materials, methods, and equipment also need improvement. Further, recent energy and material shortages have caused additional burdens on the engineering profession and brought about the need to seek alternative or cost-saving methods for foundation design and construction.

This three-day seminar was devoted to five main topics: 1) materials properties and plasticity models, which featured experimental investigations of the material properties of structural steels and plasticity models of the material characteristics under dynamic and cyclic loading conditions; 2) experimental observations, which featured experimental studies of cyclic buckling behavior of steel structural members and frames subjected to dynamic and cyclic loading conditions; 3) analytical modeling, which discussed analytical modeling of the cyclic buckling behavior of steel structural members and frames; 4) design implementation, which emphasized earthquake engineering design of steel structures against cyclic buckling; and 5) future research needs, in which future analytical and experimental research needs on the behavior and design of steel structures subjected to dynamic and cyclic loading conditions were identified. This book contains 30 contributed papers presented at the seminar.
